

Avoid Using POSIX `time_t` for Telling Time*

John Sauter[†]

2025-07-18

Abstract

The POSIX data type `time_t` is defined in a way that leads to errors in application programs when it is used for telling time. Here is how to avoid using it for that purpose.

Keywords: Coordinated Universal Time; UTC; POSIX; `time_t`.

1 Definition of `time_t`

The data type `time_t` is defined in POSIX[1] as a count of seconds. When telling time, it is the number of seconds since the Epoch, which is approximately midnight Greenwich Mean Time on January 1, 1970. This count of seconds since the Epoch is also defined as an encoding of Coordinated Universal Time into an integer.

The following subsection is the formal definition of “Seconds since the Epoch” from POSIX:

* * * * * Beginning of POSIX text * * * * *

4.19 Seconds Since the Epoch

A value that approximates the number of seconds that have elapsed since the Epoch. A Coordinated Universal Time name (specified in terms of seconds (*tm_sec*), minutes (*tm_min*), hours (*tm_hour*), days since January 1 of the year (*tm_yday*), and calendar year minus 1900 (*tm_year*)) is related to a time represented as seconds since the Epoch, according to the expression below.

If the year is < 1970 or the value is negative, the relationship is undefined. If the year is ≥ 1970 and the value is non-negative, the value is related to a Coordinated Universal Time name according to the C-language expression, where *tm_sec*, *tm_min*, *tm_hour*, *tm_yday*, and *tm_year* are all integer types:

$$\begin{aligned} &tm_sec + tm_min * 60 + tm_hour * 3600 + tm_yday * 86400 + \\ &(tm_year - 70) * 31536000 + ((tm_year - 69) / 4) * 86400 - \\ &((tm_year - 1) / 100) * 86400 + ((tm_year + 299) / 400) * 86400 \end{aligned}$$

The relationship between the actual date and time in Coordinated Universal Time, as determined by the International Earth Rotation Service, and the system’s current value for seconds since the Epoch is unspecified.

How any changes to the value of seconds since the Epoch are made to align to a desired relationship with the current actual time is implementation-defined. As represented in seconds since the Epoch, each and every day shall be accounted for by exactly 86 400 seconds.

Note: The last three terms of the expression add in a day for each year that follows a leap year starting with the first leap year since the Epoch. The first term adds a day every 4 years starting in 1973, the second subtracts a day back out every 100 years starting in 2001, and the third adds a day back in every 400 years starting in 2001. The divisions in the formula are integer divisions; that is, the remainder is discarded leaving only the integer quotient.

* * * * * End of POSIX text * * * * *

2 Problems

There are several problems with this definition:

- It is not defined for years before 1970.
- The relationship between the actual time of day and the current value for seconds since the Epoch is unspecified. This means it can vary from time to time and from one implementation to another, making the relationship meaningless.
- An application using `time_t` is required to pretend that all days contain exactly 86 400 seconds. This is false: December 31, 2016, for example, contains 86 401 seconds. This pretense leads to application program errors on days that do not contain 86 400 seconds. Because `time_t` counts seconds almost all the time, application programmers are tempted to use it as though it always counts seconds, leading to errors in the application when it doesn't.
- Because the epoch is undefined, an implementation can change it while an application is running, so that time seems to step backwards. One can forgive an application which fails when this happens.

3 Solutions

The major reason for the problems with `time_t` is that it is trying to do too much: be a count of seconds and encode Coordinated Universal Time. The first stage in solving the problems is to separate these two jobs.

3.1 Encoding Coordinated Universal Time

A good way to represent Coordinated Universal Time is with the POSIX `tm` data structure. It contains integers for the year, month, day, hour, minute and second. To encode it into an integer you can do this:

$$value = (year \times 10000000000) + (month \times 1000000000) + \\ (day \times 1000000) + (hour \times 10000) + (minute \times 100) + second$$

The value computed above is defined for all years, has a clear relationship to the date and time of day, and does not require an application to pretend that all days have 86 400 seconds. Its values are very different from the value of a `time_t`, and so are not likely to be mistaken for it, or vice-versa. It does not count seconds for more than a minute, so application programmers will not be tempted to misuse it for that purpose.

An alternative coding of time as an integer is based on International Atomic Time. See section 6.

3.2 Measuring Time

Application programmers need a way to measure time intervals. If the interval starts and ends during the execution of an application, `CLOCK_BOOTTIME` can be used, since it is a count of seconds since an arbitrary epoch. Unlike `time_t`, `CLOCK_BOOTTIME` does not change its epoch while applications are running, and so it never appears to flow backwards. However, `CLOCK_BOOTTIME` is not good for writing to a file or sending over a network to another computer, since each computer will have its own epoch, and that epoch will change when the computer is restarted. For those purposes it is best to use Coordinated Universal Time.

To measure the time between two instants of Coordinated Universal Time requires a table of days whose lengths are not 86 400 seconds. This table can be used to adjust for the number of leap seconds that have occurred during the interval.

4 Implementing the Solutions

The solutions presented above are adequate only if they will allow an application programmer to avoid completely the use of `time_t` for telling time. To demonstrate that this is possible, I will list all of the POSIX functions that use `time_t` (or `timespec`, which contains a `time_t`) and show how to replace the application functions which use `time_t` as seconds since the epoch. For the convenience of the reader I have packaged the demonstration code below into a library called `libtime`. See section 9 for details.

4.1 `clock_getres`

This function returns a `timespec`, but that `timespec` describes an interval rather than an instant. The `time_t` returned in the `timespec` is a number of seconds rather than seconds since the epoch.

4.2 `clock_gettime` and `gettimeofday`

`Gettimeofday` is equivalent to `clock_gettime` with clock ID set to `CLOCK_REALTIME`, except for the time zone, which should not be used.

`Clock_gettime` with clock ID set to `CLOCK_REALTIME` can be replaced by a function which returns the current time in a `tm` structure along with the number of nanoseconds since the last second.

```
/* Subroutine to return the current UTC time in a tm structure
 * and the number of nanoseconds since the start of the last second.
 */
int
time_current_tm_nano (struct tm *current_tm, int *nanoseconds)
{
```

```

struct timex current_timex;
struct timeval current_timeval;
int adjtimex_result;

/* Fetch time information from the kernel. */
current_timex.status = 0;
current_timex.modes = 0;
adjtimex_result = adjtimex (&current_timex);

if (adjtimex_result == -1)
{
    /* Some high security environments disable the adjtimex function,
     * even when, as here, it is just fetching information. Fall back
     * to using gettimeofday. This is a poor fallback, since it does
     * not tell us that we are in a leap second, but it is better than
     * failing. */
    gettimeofday (&current_timeval, NULL);
    gmtime_r (&current_timeval.tv_sec, current_tm);
    *nanoseconds = current_timeval.tv_usec * 1e3;
    return (0);
}

/* Format the information returned by adjtimex into a tm structure. */
gmtime_r (&current_timex.time.tv_sec, current_tm);

/* If the kernel told us we are in a leap second, increment
 * the seconds value. This will change it from 59 to 60. */
if (adjtimex_result == TIME_OOP)
{
    current_tm->tm_sec = current_tm->tm_sec + 1;
}

/* Return the number of nanoseconds since the start of the last
 * second. If the kernel's clock is not being controlled by
 * NTP it will return microseconds instead of nanoseconds. */
if (current_timex.status & STA_NANO)
    *nanoseconds = current_timex.time.tv_usec;
else
    *nanoseconds = current_timex.time.tv_usec * 1e3;

return (0);
}

```

Notice in the code above the workaround for `adjtimex` not working. I feel that it is intolerable for an environment to conceal the fact that a leap second is in progress, so I recommend that your application refuse to run in such an

environment. You can do that by calling the following subroutine at the start of your program.

```
int
time_test_for_disabled_adjtimex ()
{
    struct timex current_timex;
    int adjtimex_result;

    /* Fetch time information from the kernel. */
    current_timex.status = 0;
    current_timex.modes = 0;
    adjtimex_result = adjtimex (&current_timex);

    if (adjtimex_result == -1)
    {
        /* Some high security environments disable the adjtimex function,
         * even when, as here, it is just fetching information.
         * The adjtimex function is the only way to determine that
         * there is a leap second in progress, so return 1 if it
         * doesn't work. */
        return (1);
    }

    /* Return 0 to indicate that adjtimex has not been disabled. */
    return (0);
}
```

If the subroutine returns a non-zero result, your application should complain and exit:

```
static int
test_for_disabled_adjtimex ()
{
    int adjtimex_is_disabled;

    adjtimex_is_disabled = time_test_for_disabled_adjtimex();

    if (adjtimex_is_disabled != 0)
    {
        /* Some high security environments disable the adjtimex function,
         * even when, as here, it is just fetching information.
         * The adjtimex function is the only way to determine that
         * there is a leap second in progress, so complain if it
         * doesn't work. */
        printf ("The current time will not be correct during a leap second\n"
                "because the Linux adjtimex function is not working.\n");
    }
}
```

```

    exit (EXIT_FAILURE);
}

return (o);
}

```

The above subroutine is not included in the library, though the library does contain `time_test_for_disabled_adjtimex`. Feel free to express yourself as you see fit about the disabling of `adjtimex`. Fedora bugzilla 1778 298¹ contains my opinion.

4.3 `clock_nanosleep`

`Clock_nanosleep` with clock ID set to `CLOCK_REALTIME` and with flag `TIMER_ABSTIME` not set can be replaced by `clock_nanosleep` with clock ID set to `CLOCK_BOOTTIME`, since `CLOCK_BOOTTIME` ticks at same rate as `CLOCK_REALTIME`.

`Clock_nanosleep` with clock ID set to `CLOCK_REALTIME` and with flag `TIMER_ABSTIME` set can be replaced by a function which accepts a time in a `tm` structure and a count of nanoseconds since that second.

```

/* Sleep until a specified time. */
int
time_sleep_until (struct tm *time_tm, int nanoseconds,
                  int variable_length_seconds_before_year)
{
    long long int seconds_to_sleep;
    struct tm now_tm;
    int now_nanoseconds, ns_to_sleep;
    struct timespec request_timespec;
    struct timespec rem_timespec;
    int return_value;

    /* Fetch the current time. */
    time_current_tm_nano (&now_tm, &now_nanoseconds);

    /* Compute the number of seconds until the target time. */
    seconds_to_sleep =
        time_diff (&now_tm, time_tm,
                  variable_length_seconds_before_year);

    /* Adjust for the number of nanoseconds that have passed since
     * the last second, and the number that should pass after the
     * target second is reached before we awaken. */
    ns_to_sleep = nanoseconds - now_nanoseconds;

```

¹https://bugzilla.redhat.com/show_bug.cgi?id=1778298

```

if (ns_to_sleep < 0)
{
    ns_to_sleep = ns_to_sleep + 1e9;
    seconds_to_sleep = seconds_to_sleep - 1;
}

/* If the target time has already arrived, don't sleep. */
if (seconds_to_sleep < 0)
    return (0);
if ((seconds_to_sleep == 0) && (ns_to_sleep <= 0))
    return (0);

request_timespec.tv_sec = seconds_to_sleep;
request_timespec.tv_nsec = ns_to_sleep;

return_value = nanosleep (&request_timespec, &rem_timespec);
return (return_value);
}

```

See subsection 4.6 for `time_diff` and an explanation of `variable_length_seconds_before_year`.

4.4 `clock_settime`

`Clock_settime` is not used by applications. However, see section 12 for a recommendation that would make setting the time of day during a leap second possible.

4.5 `ctime` and `ctime_r`

`Ctime` and `ctime_r` can be replaced by a call to `localtime` followed by a call to `asctime`. See subsection 4.8 for the substitute for `localtime`. If `asctime` isn't flexible enough, use `strftime` or see subsection 5.4

4.6 `difftime`

`Difftime` can be replaced by a function which returns the time in seconds between two times expressed using the `tm` structure.

```

/* Subroutine to compute the difference, in seconds, between two
 * instants of Coordinated Universal time.
 *
 * The parameter variable_length_seconds_before_year controls
 * the interpretation of seconds before the specified year.
 * Before the invention of the atomic clock in 1955,
 * it was adequate to define the second as 1/86,400 of the length

```

```

* of a mean solar day. By 1960 it had become clear to the
* scientific world that the Earth's rotation was no longer
* steady enough for the most accurate clocks, so the definition
* of a second was changed from Earth-based to atomic-based.
*
* Civil time has always been based on the days and the seasons,
* so it was necessary to make the new second fit into the
* variable-length day. By 1972 the current procedure was settled
* on, in which there are a varying number of fixed-length seconds
* in each day.
*
* Depending on your application's needs, you will want time before
* 1972 to be measured using modern fixed-length seconds, or
* the variable-length seconds that were being used at the time.
* For example, consider this problem: "A beam of light left the
* Earth on January 1, 1970, at 00:00 UTC. How far from Earth was
* it on January 1, 2017, at 00:00 UTC?" To answer that question
* you would use modern, fixed-length seconds. If the problem is
* "Fredrick was born on February 29, 1856. How old was he
* on December 1, 1879?", you would use contemporary seconds.
*
* You should use variable-length seconds when you are concerned
* with the time as told by a contemporary clock, such as reckoning
* birthdays, and fixed-length seconds when you are concerned with
* activities that are not based on a clock, such as the time it takes
* an object to fall through a given distance.
*
* If you want to use fixed-length seconds for all dates, set
* variable_length_seconds_before_year to INT_MIN. If you want
* fixed-length seconds starting January 1, 1972, but variable-length
* seconds before January 1, 1972, set variable_length_seconds_before_year
* to 1972. If you want to ignore leap seconds entirely, set
* variable_length_seconds_before_year to INT_MAX.
*/
long long int

```

The left number is the integer part of the Julian Day Number of the day which starts with the new value of DTAI, and the right number is the new value of DTAI.

The full table of changes in DTAI is embedded in this PDF file; see section 9. The table can be generated automatically[6], but the ultimate source of its data is based on manually editing a file when the International Earth Rotation and Reference Systems Service (IERS) issues its Bulletin C² announcing the next leap second. See file `extraordinary_days.dat`, also embedded in this PDF file, for details.

4.7 `gmtime` and `gmtime_r`

`Gmtime` and `gmtime_r` convert from `time_t` to the `tm` structure, representing Coordinated Universal Time. We don't need this function since our primary representation for time is the `tm` structure representing Coordinated Universal Time, and we are not using `time_t`.

4.8 `localtime` and `localtime_r`

`Localtime` and `localtime_r` convert a `time_t` into a `tm` structure that represents local time. We can replace this with a function that takes as input a `tm` structure that represents Coordinated Universal Time. If you want the local time in a foreign location you can also specify the UTC offset.

²<https://www.iers.org/IERS/EN/Publications/Bulletins/bulletins.html>

```

/* Convert a tm structure containing Coordinated Universal Time
 * to one containing a foreign local time. Foreign_UTC_offset is
 * the offset in seconds between UTC and the desired local time.
 */
int
time_UTC_to_foreign_local (struct tm *coordinated_universal_time,
                           int foreign_UTC_offset,
                           struct tm *local_time_tm,
                           int variable_length_seconds_before_year)
{
    struct tm utc_time_tm;
    int gmt_offset, hours_offset, minutes_offset, seconds_offset;
    int prev_minute_length;

    time_copy_tm (coordinated_universal_time, &utc_time_tm);
    gmt_offset = foreign_UTC_offset;

    /* When converting to local time, handle hours, minutes and
     * seconds separately. That way leap seconds occur at
     * about the same time everywhere, regardless of time zone.
     */
    hours_offset = gmt_offset / 3600;
    minutes_offset = (gmt_offset / 60) - (hours_offset * 60);
    seconds_offset =
        gmt_offset - (hours_offset * 3600) - (minutes_offset * 60);

    /* Special processing if the time zone is not on a minute
     * boundary. We delay the leap second until the end of
     * the local minute. */
    if (seconds_offset != 0)
    {
        /* If the time zone is not on a minute boundary,
         * and the minute we are leaving does not have
         * 60 seconds, compensate for it. */
        prev_minute_length =
            time_length_prev_UTC_minute (&utc_time_tm,
                                         variable_length_seconds_before_year);
        if (prev_minute_length != 60)
        {
            seconds_offset =
                seconds_offset + prev_minute_length - 60;
        }

        /* Always add seconds, rather than subtract. */
        if (seconds_offset < 0)
        {

```

```

        seconds_offset = seconds_offset + 60;
        minutes_offset = minutes_offset - 1;
        if (minutes_offset < 0)
        {
            minutes_offset = minutes_offset + 60;
            hours_offset = hours_offset - 1;
        }
    }
}

utc_time_tm.tm_hour = utc_time_tm.tm_hour + hours_offset;
utc_time_tm.tm_min = utc_time_tm.tm_min + minutes_offset;
utc_time_tm.tm_sec = utc_time_tm.tm_sec + seconds_offset;

/* Copy the year, month, day, hour, minute and second
 * back to the caller. */
local_time_tm->tm_year = utc_time_tm.tm_year;
local_time_tm->tm_mon = utc_time_tm.tm_mon;
local_time_tm->tm_mday = utc_time_tm.tm_mday;
local_time_tm->tm_hour = utc_time_tm.tm_hour;
local_time_tm->tm_min = utc_time_tm.tm_min;
local_time_tm->tm_sec = utc_time_tm.tm_sec;

/* Make sure the other fields in the tm structure do not contain garbage. */
local_time_tm->tm_wday = 0;
local_time_tm->tm_yday = 0;
local_time_tm->tm_isdst = -1;
local_time_tm->tm_gmtoff = gmtoff;
local_time_tm->tm_zone = NULL;

/* Make sure all the fields are in their valid ranges
 * and update the fields output by mktime. */
time_local_normalize (local_time_tm, local_time_tm->tm_sec,
                     variable_length_seconds_before_year);

return (0);
}

/* Convert a tm structure containing Coordinated Universal Time
 * to one containing local time. */
int
time_utc_to_local (struct tm *coordinated_universal_time,
                  struct tm *local_time_tm,
                  int variable_length_seconds_before_year)
{
    struct tm utc_time_tm;

```

```

struct tm temporary_local_time_tm;
time_t seconds_since_epoch;
int gmt_offset;

/* Compute the number of seconds from the epoch until the
 * beginning of the current minute, since the timegm and
 * localtime functions will not work correctly during a
 * leap second. */
time_copy_tm (coordinated_universal_time, &utc_time_tm);
utc_time_tm.tm_sec = 0;
seconds_since_epoch = timegm (&utc_time_tm);

/* Convert to local time in a tm structure. */
localtime_r (&seconds_since_epoch, &temporary_local_time_tm);
gmt_offset = temporary_local_time_tm.tm_gmtoff;

/* Now that we have access to the GMT offset, we do the
 * conversion again, this time taking leap seconds into
 * account. */
return (time_UTC_to_foreign_local (coordinated_universal_time,
                                   gmt_offset,
                                   local_time_tm,
                                   variable_length_seconds_before_year));
}

```

See subsection 5.1 for `time_copy_tm`, subsection 5.2 for `time_length_prev_UTC_minute`, and subsection 5.3 for `time_local_normalize`.

4.9 mktime

Mktime converts a `tm` structure that represents local time into a `time_t`. We can replace this with a function whose output is a `tm` structure that represents Coordinated Universal Time.

```

/* Convert a tm structure containing local time
 * to one containing Coordinated Universal Time.
 * As a side effect, update the tm_wday, tm_yday,
 * tm_isdst, tm_zone and tm_gmtoff fields in
 * the local_time parameter. */
int
time_local_to_UTC (struct tm *local_time,
                  struct tm *coordinated_universal_time,
                  int variable_length_seconds_before_year)
{
    struct tm local_tm;
    struct tm utc_time_tm;
    time_t seconds_since_epoch;

```

```
int gm_offset;
int hours_offset, minutes_offset, seconds_offset;

/* Compute the number of seconds from the epoch to the
 * beginning of the current minute, since the mktime and
 * gmtime functions will not work correctly during a
 * leap second. */
time_copy_tm (local_time, &local_tm);
local_tm.tm_sec = 0;
seconds_since_epoch = mktime (&local_tm);

/* Convert to UTC in a tm structure. */
gmtime_r (&seconds_since_epoch, &utc_time_tm);

/* Now that we have access to the GMT offset,
 * do the conversion again, taking leap seconds
 * into account. */
gm_offset = local_tm.tm_gmtoff;
utc_time_tm.tm_year = local_time->tm_year;
utc_time_tm.tm_mon = local_time->tm_mon;
utc_time_tm.tm_mday = local_time->tm_mday;
utc_time_tm.tm_hour = local_time->tm_hour;
utc_time_tm.tm_min = local_time->tm_min;
utc_time_tm.tm_sec = local_time->tm_sec;

/* Add in the hours, minutes and seconds of the offset
 * separately. That way leap seconds occur at about
 * the same time everywhere. */
hours_offset = gm_offset / 3600;
minutes_offset = (gm_offset / 60) - (hours_offset * 60);
seconds_offset =
    gm_offset - (minutes_offset * 60) - (hours_offset * 3600);

/* Always add seconds. */
if (seconds_offset > 0)
{
    seconds_offset = seconds_offset - 60;
    minutes_offset = minutes_offset + 1;
    if (minutes_offset > 59)
    {
        minutes_offset = minutes_offset - 60;
        hours_offset = hours_offset + 1;
    }
}

utc_time_tm.tm_hour = utc_time_tm.tm_hour - hours_offset;
```

```

utc_time_tm.tm_min = utc_time_tm.tm_min - minutes_offset;
utc_time_tm.tm_sec = utc_time_tm.tm_sec - seconds_offset;

/* Make sure the other fields in the tm structure do not contain garbage. */
utc_time_tm.tm_wday = 0;
utc_time_tm.tm_yday = 0;
utc_time_tm.tm_isdst = -1;
utc_time_tm.tm_gmtoff = 0;
utc_time_tm.tm_zone = NULL;

/* Make sure the fields of the tm structure are all in their
 * valid ranges and update the fields output by mktime. */
time_UTC_normalize (&utc_time_tm, utc_time_tm.tm_sec,
                    variable_length_seconds_before_year);

/* Return the result to the caller. */
time_copy_tm (&utc_time_tm, coordinated_universal_time);

/* Also return the additional information calculated by mktime.
 */
local_time->tm_wday = local_tm.tm_wday;
local_time->tm_yday = local_tm.tm_yday;
local_time->tm_isdst = local_tm.tm_isdst;
local_time->tm_zone = local_tm.tm_zone;
local_time->tm_gmtoff = local_tm.tm_gmtoff;

return (0);
}

```

See subsection 5.2 for `time_UTC_normalize`.

4.10 nanosleep

Nanosleep takes a `timespec` as input, but the `time_t` portion of that `timespec` represents the number of seconds to sleep, not an instant of time. Similarly, the `timespec` output represents the number of seconds remaining in the sleep time. Both `time_t` values can be considered a count of seconds.

4.11 settimeofday

`Settimeofday` is not used by applications. However, see section 12 for a recommendation that would make setting the time of day during a leap second possible.

4.12 stat

Stat has three timespec fields: `atime`, `mtime` and `ctime`. The POSIX standard is rather vague on when the fields are updated to the current time, and some file systems have precision less than a second for some of the fields. Your application should not count on these fields being accurate to the second. If you need to compare file times, you should do what `rsync` does, and implement a modify-window feature, which causes two file times to compare equal if they differ by no more than the specified number of seconds.

Some file systems fill in the nanoseconds part of the timespec field, but you should ignore nanoseconds when comparing because the times may be inaccurate by up to one second, even on modern file systems. However, see section 12 for a recommendation for making the file times accurate.

4.13 strftime

Strftime has formatting code `%s`, which outputs the number of seconds since the Epoch. Don't use this.

4.14 time

Time returns the current time as a `time_t`. Instead, return it as a `tm`.

```
/* Subroutine to return the current UTC time in a tm structure.
 * If you need more precision than seconds, see
 * time_current_tm_nano. */
int
time_current_tm (struct tm *current_tm)
{
    struct timex current_timex;
    struct timeval current_timeval;
    int adjtimex_result;

    /* Fetch time information from the kernel. */
    current_timex.status = 0;
    current_timex.modes = 0;
    adjtimex_result = adjtimex (&current_timex);

    if (adjtimex_result == -1)
    {
        /* Some high security environments disable the adjtimex function,
         * even when, as here, it is just fetching information. Fall back
         * to using gettimeofday. This is a poor fallback, since it does
         * not tell us that we are in a leap second, but it is better than
         * failing. */
        gettimeofday (&current_timeval, NULL);
        gmtime_r (&current_timeval.tv_sec, current_tm);
    }
}
```

```

        return (0);
    }
    /* Format that information into a tm structure. */
    gmtime_r (&current_timex.time.tv_sec, current_tm);

    /* If the kernel told us we are in a leap second, increment
     * the seconds value. This will change it from 59 to 60. */
    if (adjtimex_result == TIME_OOP)
    {
        current_tm->tm_sec = current_tm->tm_sec + 1;
    }

    return (0);
}

```

4.15 timegm

Timegm converts a `tm` structure containing Coordinated Universal Time into a `time_t`. We don't need it, since we are using the `tm` structure as our primary representation of time. However, it is sometimes convenient to represent time as a single value instead of a structure.

```

/* Subroutine to convert a time in tm format to an integer.
 * Unlike time_t, this integer has a unique value during a
 * leap second. */
int
time_tm_to_integer (struct tm *input_tm, long long int *result)
{
    int year, month, day, hour, minute, second;
    long long int result_value;

    year = input_tm->tm_year + 1900;
    month = input_tm->tm_mon + 1;
    day = input_tm->tm_mday;
    hour = input_tm->tm_hour;
    minute = input_tm->tm_min;
    second = input_tm->tm_sec;

    result_value = year;
    result_value = (result_value * 1e2) + month;
    result_value = (result_value * 1e2) + day;
    result_value = (result_value * 1e2) + hour;
    result_value = (result_value * 1e2) + minute;
    result_value = (result_value * 1e2) + second;
    *result = result_value;
}

```

```

    return (o);
}

```

The following subroutine goes one step further, by including the fraction of a second in the value. Note that this code depends on having a C compiler which supports 128-bit integers.

```

/* Subroutine to convert a time in tm format to an integer.
 * Unlike time_t, this integer has a unique value during a
 * leap second. time_t counts seconds except during a
 * leap second. This integer never counts seconds, and
 * includes fractions of a second.
 */
int
time_tm_nano_to_integer (struct tm *input_tm, int input_nanoseconds,
                        __int128 *result)
{
    int year, month, day, hour, minute, second;
    __int128 result_value;

    year = input_tm->tm_year + 1900;
    month = input_tm->tm_mon + 1;
    day = input_tm->tm_mday;
    hour = input_tm->tm_hour;
    minute = input_tm->tm_min;
    second = input_tm->tm_sec;

    result_value = year;
    result_value = (result_value * 1e2) + month;
    result_value = (result_value * 1e2) + day;
    result_value = (result_value * 1e2) + hour;
    result_value = (result_value * 1e2) + minute;
    result_value = (result_value * 1e2) + second;
    result_value = (result_value * (__int128) 1e9) +
        (__int128) input_nanoseconds;
    *result = result_value;

    return (o);
}

```

A 128-bit integer cannot be printed with `printf`, so here is a subroutine to convert it to a string. Note that this code depends on having a C compiler which supports 128-bit integers.

```

/* Convert a 128-bit integer to a string.
 * The return value is the number of characters written into the string,

```

```

    * not counting the trailing NUL character.
    * Value_p is a pointer to the integer to be converted.
    * Result is a pointer to the output string; result_size is its length.
    * The string should be at least 41 characters long, to hold a
    * maximum-sized result. */

/* This subroutine is dedicated to Steve Russell, who wrote the
 * original recursive decimal print subroutine for the DEC PDP-1
 * in 1964. */
int
int128_to_string (__int128 *value_p, char *result, int result_size)
{
    __int128 positive_value;
    __int128 remaining_digits;
    int size_remaining;
    int character_count;
    int remaining_count;
    int current_digit;
    char *result_pointer;
    volatile __int128 volatile_value;
    __int128 value;

    size_remaining = result_size; /* Guard against exceeding the size
                                   * of the result string. */

    result_pointer = result;
    character_count = 0; /* Keep track of the number of characters
                           * we write, so we can return it. */

    /* Don't require the value parameter to be 16-byte aligned.
     * Python represents a 128-bit number as a structure of two
     * 64-bit numbers, and so does not know that such a structure
     * should be 16-byte aligned. */
    memcpy (&value, value_p, sizeof(value));

 * not counting the trailing NUL byte, we make the recursive call
 * simpler since it has to find the end of the string. */
return (character_count);
}

```

5 Beyond POSIX

Just being able to do all the POSIX functions isn't enough to persuade application programmers to abandon `time_t` for telling time. Application programmers need a net benefit to make changing worthwhile. To sweeten the solution, here are some subroutines to manipulate a time value.

5.1 Copy a time

Here is how to copy a time value from one `tm` structure to another.

```

/* Copy a time from one tm structure to another. */
int
time_copy_tm (struct tm *in_tm, struct tm *out_tm)
{
    memset (out_tm, 0, sizeof (*out_tm));
    out_tm->tm_year = in_tm->tm_year;
    out_tm->tm_mon = in_tm->tm_mon;
    out_tm->tm_mday = in_tm->tm_mday;
    out_tm->tm_hour = in_tm->tm_hour;
    out_tm->tm_min = in_tm->tm_min;
    out_tm->tm_sec = in_tm->tm_sec;
    out_tm->tm_yday = in_tm->tm_yday;
    out_tm->tm_wday = in_tm->tm_wday;
    out_tm->tm_isdst = in_tm->tm_isdst;

```

5.2 Adding years, months, days, hours, minutes or seconds

If you have a time value stored in a `tm` structure, and it represents Coordinated Universal Time, you can add to the year, month, day, hour, minute or second field. You can decrease these fields by adding a negative value. When the target date is invalid, such as February 31, you can choose whether to round towards the future or towards the past to get a valid date.

```

/* Add to a field of a tm structure, and then make all the fields
 * have valid values. */

/* Rounding Mode is used when a modification to a field has caused
 * another field to be invalid. For example, if you start with
 * October 31 and increase the month by one, you have November 31,
 * which does not exist. If Rounding Mode is -1, the result is
 * November 30. If Rounding Mode is +1, the result is December 1.
 * Another example is birthdays on February 29. If you were born
 * on February 29, 1996, your twentieth birthday is on February 29,
 * 2016. What day is your twenty-first birthday? Start with
 * February 29, 1996 and increase the year by twenty-one
 * to get February 29, 2017, then set Rounding Mode to +1
 * if you want March 1, 2017, or -1 if you want February 28, 2017.
 *
 * Like months, not all minutes are the same length. If you start
 * with December 31, 2016, 23:59:60, and decrease the minutes by one

```

```

* you get December 31, 2016, 23:58:60, which does not exist.
* If Rounding Mode is +1 you get December 31, 2016, 23:59:00. If
* Rounding Mode is -1 you get December 31, 2016, 23:58:59.

5.3 Doing the same with local time

If you have a time value stored in a `tm` structure, and it represents local time, you can add to the year, month, day, hour, minute or second field. You can decrease these fields by adding a negative value. When the target date is invalid, such as February 31, you can choose whether to round towards the future or towards the past to get a valid date.

```

/* Add to a field of a tm structure, and then make all the fields
 * have valid values. */

/* Rounding Mode is used when a modification to a field has caused
 * another field to be invalid. For example, if you start with
 * October 31 and increase the month by one, you have November 31,
 * which does not exist. If Rounding Mode is -1, the result is
 * November 30. If Rounding Mode is +1, the result is December 1.
 * Another example is birthdays on February 29. If you were born
 * on February 29, 1996, your twentieth birthday is on February 29,
 * 2016. What day is your twenty-first birthday? Start with
 * February 29, 1996 and increase the year by twenty-one

```

```

* to get February 29, 2017, then set Rounding Mode to +1
* if you want March 1, 2017, or -1 if you want February 28, 2017.
*
* Like months, not all minutes are the same length. If you start
* with December 31, 2016, 18:59:60 EST, and decrease the minutes
* by one you get December 31, 2016, 18:58:60 EST, which does not
* exist. If Rounding Mode is +1 you get December 31, 2016,
* 18:59:00 EST. If Rounding Mode is -1 you get December 31, 2016,
* 18:58:59 EST.
*/

5.4 Representing a time as a string

If you want to send a time to another computer, or write it into a file, it is convenient to be able to convert it to a string. Here is how you can do that. This subroutine works for both Coordinated Universal Time and local time.

```

/* Subroutine to convert a time in tm format to a string,
 * in RFC 3339 (ISO 8601) format. Returns the number of
 * characters written into the string, not counting the
 * trailing NUL byte. If the time zone is not an integral
 * number of minutes offset from UTC, violates RFC 3339
 * by appending ":ss" to the offset. */
int
time_tm_to_string (struct tm *input_tm,
                  char *current_time_string,

```

```

    timezone = &buffer [0];
}

return_val = snprintf (current_time_string,
    current_time_string_length,
    "%04d-%02d-%02dT%02d:%02d:%02d%s",
    input_tm->tm_year + 1900,
    input_tm->tm_mon + 1,
    input_tm->tm_mday,
    input_tm->tm_hour,
    input_tm->tm_min,
    input_tm->tm_sec,
    timezone);

return (return_val);
}

```

If you need more precision you can include the nanoseconds:

```

/* Subroutine to convert a time in tm format plus the number
 * of nanoseconds since the last second to a string,
 * in RFC 3339 (ISO 8601) format. Returns the number of
 * characters written into the string, not counting the
 * trailing NUL byte. If the time zone is not an integral
 * number of minutes offset from UTC, violates RFC 3339
 * by appending ":ss" to the offset. */
int
time_tm_nano_to_string (struct tm *input_tm,
    int input_nanoseconds,
    char *current_time_string,
    int current_time_string_length)
{
    int return_val;
    int gmt_offset, offset_hours, offset_minutes, offset_seconds;
    int pos_offset;
    char *timezone;
    char buffer [32];

    /* Compute the time zone information. We use Z for UTC,
     * otherwise + or - hh:mm or hh:mm:ss. */
    gmt_offset = input_tm->tm_gmtoff;
    if (gmt_offset == 0)
    {
        timezone = "Z";
    }
    else
    {

```

```

    if (gmt_offset < 0)
    {
        pos_offset = -gmt_offset;
    }
    else
    {
        pos_offset = gmt_offset;

            "+%03d:%02d:%02d", offset_hours, offset_minutes,
            offset_seconds);
    }
    timezone = &buffer [0];
}

return_val = snprintf (current_time_string,
    current_time_string_length,
    "%04d-%02d-%02dT%02d:%02d:%02d.%09d%s",
    input_tm->tm_year + 1900,
    input_tm->tm_mon + 1,
    input_tm->tm_mday,
    input_tm->tm_hour,
    input_tm->tm_min,
    input_tm->tm_sec,
    input_nanoseconds,
    timezone);

return (return_val);
}

```

6 International Atomic Time

Applications that are more concerned with measuring time intervals than with the rotation of the Earth would like a data type like the POSIX `time_t` but without leap seconds. A common way to construct such a data type is with reference to International Atomic Time, or TAI.

TAI is a time scale which started on January 1, 1958, at 00:00:00 GMT and has counted fixed-length SI seconds since then. For the 14 years from 1958 to 1972, UTC used seconds which averaged shorter than the SI seconds, so by 1972 the two time scales differed by about 10 seconds. During 1971 the UTC time scale was made to exactly match the TAI time scale, with an offset of 10 seconds.

Since January 1, 1972 at 00:00:00 UTC, both TAI and UTC have counted SI seconds, each in its own way. UTC inserts leap seconds to keep civil time synchronized to the rotation of the Earth, and TAI does not. Each time UTC inserts a leap second, the difference between TAI and UTC increases by one second.

UNIX programmers like to use 1970 as a base date, so they backdated the synchronization of TAI and UTC to January 1, 1970, but kept the 10-second offset. Thus, the new data type, which I will call the TAI integer, is the number of SI seconds since January 1, 1970, plus 10.

The benefit of this data type is that it makes computing the number of seconds between two times after January 1, 1972 easy: just subtract the integers. The tradeoff is that displaying the time in UTC is more difficult. For example, the TAI integer 1 483 228 836 corresponds to December 31, 2016, at 23:59:60. See the example in subsection 10.4 for this conversion.

7 List of Entry Points

For reference, here are the subroutines described above, in alphabetical order, each with a brief description. The attribute “const” means that the function does not examine any values except its arguments, and has no effects except to return a value. The attribute “pure” means the same except that the function can examine (but not change) global variables.

8 Python

The Python module `datetime` contains a class also called `datetime` which ignores leap seconds, and therefore has the same problem as POSIX `time_t`. A program written in the Python programming language must therefore refrain from using `datetime` in order to handle leap seconds correctly.

You can use the POSIX `tm` data structure in place of `datetime`, and use these same C subroutines to manipulate it using `ctypes`. Write a module to define the interface, as follows:

```
import ctypes
import ctypes.util

# Translation into ctypes of the POSIX tm structure
# as implemented on GNU/Linux.

class tm (ctypes.Structure):
    _fields_ = [
        ("tm_sec", ctypes.c_int),
        ("tm_min", ctypes.c_int),
        ("tm_hour", ctypes.c_int),
        ("tm_mday", ctypes.c_int),
        ("tm_mon", ctypes.c_int),
        ("tm_year", ctypes.c_int),
        ("tm_wday", ctypes.c_int),
        ("tm_yday", ctypes.c_int),
        ("tm_isdst", ctypes.c_int),
        ("tm_padi", ctypes.c_int),
        ("tm_gmtoff", ctypes.c_long),
        ("tm_zone", ctypes.POINTER(ctypes.c_char_p))
    ]
    def __str__(self):
        string_p = ctypes.create_string_buffer (256)
        time_tm_to_string (self, string_p, ctypes.sizeof(string_p))
        return (string_p.value.decode("utf-8"))

# A 128-bit integer.
class int128 (ctypes.Structure):
    _fields_ = [
```

```

        ("low_bits", ctypes.c_ulonglong),
        ("high_bits", ctypes.c_ulonglong)
    ]
    def __str__(self):
        string_p = ctypes.create_string_buffer (256)
        int128_to_string (self, string_p, ctypes.sizeof (string_p))
        return (string_p.value.decode("utf-8"))

# Note that if you install libtime in /usr/local/lib, which is the
# default location if you install from the tarball, you will need
# to set LD_LIBRARY_PATH to include it.

```

This file is provided as `time_subroutines.py`. Import `ctypes` and the module, and you can then call the subroutines from Python. Here is a Python script to demonstrate this:

```

# Demonstrate the time_subroutines interface.
import ctypes
import time_subroutines

# Make sure the adjtimex function has not been disabled.
if (time_subroutines.time_test_for_disabled_adjtimex() != 0):
    print ('The current time will not be correct during a leap second')
    print ('because the Linux adjtimex function is not working.')
    raise SystemExit

# Define two variables of type tm.
tm_1 = time_subroutines.tm()
tm_2 = time_subroutines.tm()

# Fetch the current time.
time_subroutines.time_current_tm(tm_1)

# Express the current time as a string.
string_buffer = ctypes.create_string_buffer(256)
time_subroutines.time_tm_to_string(tm_1, string_buffer,
                                   ctypes.sizeof(string_buffer))
the_time = string_buffer.value.decode("utf-8")

# Print the current time.
print (the_time)

```

```

# Convert the current time to the local time zone.
time_subroutines.time.UTC_to_local (tm_1, tm_2, time_subroutines.int_min)

# Express it as a string using the str method, and print it along with
# the day of the week and the day of the year.
weekday_names = ('Sunday', 'Monday', 'Tuesday', 'Wednesday', 'Thursday',
                  'Friday', 'Saturday')
print (str(tm_2) + ", day of week = " + weekday_names[tm_2.tm_wday] +
        ", day of year = " + str(tm_2.tm_yday) + ".")

# Print the date and time as an integer.
return_value, now_int = time_subroutines.time_tm_to_integer (tm_2)
print ("Corresponding integer = " + str(now_int) + ".")

# Create a time value of December 31, 2016, at 23:59:59 UTC.
tm_3 = time_subroutines.tm (tm_year = 2016 - 1900, tm_mon = 12 - 1,
                             tm_mday = 31, tm_hour = 23, tm_min = 59,
                             tm_sec = 59, tm_isdst = 0, tm_gmtoff = 0,
                             tm_zone = None)

# Calculate the day of the week and the day of the month.
time_subroutines.time.UTC_normalize (tm_3, tm_3.tm_sec,
                                     time_subroutines.int_min)

# Print it.
print (str(tm_3) + ", day of week = " + weekday_names[tm_3.tm_wday] +
        ", day of year = " + str(tm_3.tm_yday) + ".")
return_value, now_int = time_subroutines.time_tm_to_integer (tm_3)
print ("Corresponding integer = " + str(now_int) + ".")

# Add one second.
time_subroutines.time.UTC_add_seconds (tm_3, 1, time_subroutines.int_min)

# And print. The result should be 2016-12-31T23:59:60.
print (str(tm_3) + ", day of week = " + weekday_names[tm_3.tm_wday] +
        ", day of year = " + str(tm_3.tm_yday) + ".")

print ("Corresponding integer = " + str(now_int) + ".")

# One more second should get us to the next year.
time_subroutines.time.UTC_add_seconds (tm_3, 1, time_subroutines.int_min)
print (str(tm_3) + ", day of week = " + weekday_names[tm_3.tm_wday] +
        ", day of year = " + str(tm_3.tm_yday) + ".")
return_value, now_int = time_subroutines.time_tm_to_integer (tm_3)
print ("Corresponding integer = " + str(now_int) + ".")

```

Use the Julian Day Number instead of the proleptic Gregorian ordinal from the `datetime` module, since it covers a wider span of time. If you wish to avoid floating point in your dates, you can use the integer part of the Julian Day Number, with the understanding that 0.5 must be added to get a proper Julian Day Number. The `tm` structure is always associated with a time zone.

There is a Python example in subsection 10.6. It illustrates conversion from POSIX `tm` to Python `time.struct_time`, which is able to represent leap seconds.

9 Embedded files

To save you the trouble of typing in these subroutines, they are embedded in this PDF file. Also included are some sample and test programs, and the configuration scripts needed to compile the programs and construct this PDF file. Building the PDF file requires \LaTeX and Python.

9.1 PDF file

If you have only the PDF file, you can build the time library and include files as follows:

1. Install package `proleptic_utc_with_leap_seconds` to get file `extraordinary_days.dat` installed. You can find a tarball at this URL: https://github.com/Show-Control/proleptic_utc_with_leap_seconds. Like this library it can also be built from its PDF file, which is at https://www.systemeyescomputer-store.com/leap_seconds/proleptic_UTC.pdf.
2. Create an empty directory.
3. Copy the PDF file to it.
4. Create within that directory subdirectories `examples`, `m4`, `src` and `tests`.
5. Extract the embedded files from the PDF file using `pdfdetach -saveall`.
6. Type `bash fix_files.sh` to correct the permissions of the extracted files.
7. Build the library the usual way with `./configure` and `make`.
8. Once the library is built you can install it by typing `sudo make install`.

9.2 TAR file

If you have the compressed tar file, extract its contents to an empty directory, then type `./configure`, and `make`. Type `sudo make install` to install the library. If you want the PDF you can get it by typing `make pdf`.

9.3 COPR

If you are running the Fedora distribution of GNU/Linux, the code described in this document is also available in a repository through the Fedora Copr build service. To enable the repository, type `sudo dnf copr enable johnsauter/libtime`. You need to have `dnf-plugins-core` installed. Once the repository is enabled you can type `sudo dnf install libtime-devel` to install the library, include files and concise documentation. To get this PDF file, install `libtime-doc`. Your users can install `libtime` to get just the library. If you are on a platform whose C compiler does not support 128-bit integers, `int128_to_string` and `time_tm_nano_to_integer` are not included in `libtime`.

9.4 GitHub

These files are also available on github, at the following URL:

<https://github.com/ShowControl/libtime>

That directory has all of the code displayed in this document, the \LaTeX source for this document, a tarball which holds the sources plus the build and install procedure, and the source RPM.

10 Examples

These examples are intended to illustrate how an application would use these subroutines to manipulate time represented in a `tm` structure.

10.1 Meeting at 9 AM

You wish to schedule a meeting in the Chrysanthemum Conference Hall at 9 AM on June 30, 2017. The participants are all over the world, so the message sent to their scheduling software will be in Coordinated Universal Time. The Chrysanthemum Conference Hall is located in Tokyo, Japan.

Set your time zone to Asia/Tokyo. Construct a `tm` structure containing June 30, 2017, at 9 AM. Convert that from local time to UTC. Convert the UTC time to a string, and send the string to the participants. The string you send should be `2017-06-30T00:00:00Z`.

10.2 Periodic Backups

You are writing the scheduler for a backup program. At 3 AM local time after each weekday it does an incremental backup, except it does a full backup if the last full backup is more than a month old. The scheduler is run when the backup program is installed on the computer, and again when the current backup has started. The scheduler is expected to compute the Coordinated Universal Time at which to start the next backup, and indicate whether the backup will be incremental or full.

Compute the current time and convert it to local time. Set the hour, minute and second to 03:00:00. Using that as the base, advance by one or more days until `tm_wday` is not Sunday or Monday. Convert the result to Coordinated Universal Time. This is the time of the next backup. If you install the software on December 31, 2016, at 21:21:35 in time zone America/New_York, the first scheduled backup will be at 2017-01-03T08:00:00Z.

```

struct tm time_tm;
struct tm local_time_tm;
struct tm backup_tm;
struct tm extra_time_tm;
struct tm int_time_tm;
char buffer1 [64];
char buffer2 [64];
int found_time, day_incr, diff;

time_current_tm (&time_tm);
time_utc_to_local (&time_tm, &local_time_tm, INT_MIN);
time_tm_to_string (&local_time_tm, &buffer1 [0], sizeof(buffer1));
printf ("now: %s\n", buffer1);
local_time_tm.tm_hour = 3;
local_time_tm.tm_min = 0;
local_time_tm.tm_sec = 0;

found_time = 0;
day_incr = 1;
while (!found_time)
{
    time_copy_tm (&local_time_tm, &extra_time_tm);
    time_local_add_days (&extra_time_tm, day_incr, 1, INT_MIN);
    if ((extra_time_tm.tm_wday == 0) ||
        (extra_time_tm.tm_wday == 1))
        day_incr = day_incr + 1;
    else
        found_time = 1;
}

time_local_to_utc (&extra_time_tm, &time_tm, INT_MIN);
time_tm_to_string (&time_tm, &buffer1 [0], sizeof (buffer1));
printf ("Next scheduled backup is at %s.\n", buffer1);

    Subtract one month from the local time computed above, and convert it to
    Coordinated Universal Time. Compute the difference between this time and the
    time of the last full backup. If the difference is negative, or if there has never
    been a full backup, this backup is full; otherwise it is incremental.

    /* To illustrate, assume the last backup was 29 days ago.
    */

```

```

time_current_tm (&backup_tm);
time_utc_add_days (&backup_tm, -29, -1, INT_MIN);
time_tm_to_string (&backup_tm, &buffer2 [0], sizeof (buffer2));
printf ("Assume the last full backup was %s.\n", buffer2);

time_local_add_months (&extra_time_tm, -1, 1, INT_MIN);
time_local_to_utc (&extra_time_tm, &int_time_tm, INT_MIN);
time_tm_to_string (&int_time_tm, &buffer1 [0], sizeof (buffer1));
printf ("One month before the next scheduled backup is %s.\n",
        buffer1);
diff = time_diff (&int_time_tm, &backup_tm, INT_MIN);
if (diff < 0)
    printf ("Next backup is full.\n");
else
    printf ("Next backup is incremental.\n");

```

10.3 Rocket over Central Park

You are asked to explode a fireworks rocket over Central Park in New York City at exactly 7 PM on the last day of each month. You place a computer-controlled rocket launcher on a building adjacent to Central Park. You know that the rocket will take exactly two seconds to reach the top of its arc after it is launched. The launch computer knows only about Coordinated Universal Time. What schedule do you give it for launching in 2016?

Starting with January 31, 2016, in time zone America/New_York, step through the months until the year is no longer 2016, rounding the date down to get the last day of the month. On each day, set the time to 7 PM, convert to UTC, then subtract two seconds. The schedule will accomodate Daylight Saving Time, the extra day at the end of February, and the leap second at the end of the year.

```

struct tm time_tm;
struct tm local_time_tm;
struct tm extra_time_tm;
char buffer1 [64];
char buffer2 [64];
int month_incr;

time_current_tm (&time_tm);
time_utc_to_local (&time_tm, &local_time_tm, INT_MIN);

local_time_tm.tm_year = 2016 - 1900;
local_time_tm.tm_mon = 1 - 1;
local_time_tm.tm_mday = 31;
local_time_tm.tm_hour = 19;
local_time_tm.tm_min = 0;

```

```

local_time_tm.tm_sec = 0;

month_incr = 0;

while (1)
{
    time_copy_tm (&local_time_tm, &extra_time_tm);
    time_local_add_months (&extra_time_tm, month_incr, -1, INT_MIN);
    extra_time_tm.tm_hour = 19;
    extra_time_tm.tm_min = 0;
    extra_time_tm.tm_sec = 0;
    if (extra_time_tm.tm_year != (2016 - 1900))
        break;

    time_local_to_UTC (&extra_time_tm, &time_tm, INT_MIN);
    time_UTC_add_seconds (&time_tm, -2, INT_MIN);
    time_tm_to_string (&time_tm, &buffer1 [0], sizeof (buffer1));
    time_tm_to_string (&extra_time_tm, &buffer2 [0],
        sizeof (buffer2));
    printf ("%s, 2 sec before %s.\n", buffer1, buffer2);
    month_incr = month_incr + 1;
}

```

Here is the schedule for 2016:

```

2016-01-31T23:59:58Z, 2 sec before 2016-01-31T19:00:00-05:00.
2016-02-29T23:59:58Z, 2 sec before 2016-02-29T19:00:00-05:00.
2016-03-31T22:59:58Z, 2 sec before 2016-03-31T19:00:00-04:00.
2016-04-30T22:59:58Z, 2 sec before 2016-04-30T19:00:00-04:00.
2016-05-31T22:59:58Z, 2 sec before 2016-05-31T19:00:00-04:00.
2016-06-30T22:59:58Z, 2 sec before 2016-06-30T19:00:00-04:00.
2016-07-31T22:59:58Z, 2 sec before 2016-07-31T19:00:00-04:00.
2016-08-31T22:59:58Z, 2 sec before 2016-08-31T19:00:00-04:00.
2016-09-30T22:59:58Z, 2 sec before 2016-09-30T19:00:00-04:00.
2016-10-31T22:59:58Z, 2 sec before 2016-10-31T19:00:00-04:00.
2016-11-30T23:59:58Z, 2 sec before 2016-11-30T19:00:00-05:00.
2016-12-31T23:59:59Z, 2 sec before 2016-12-31T19:00:00-05:00.

```

10.4 Using International Atomic Time

You are writing an application that must compute time intervals quickly, but can afford to spend more time when displaying a time stamp to a person. You decide to use a time scale based on International Atomic Time as described in section 6. You are using the integer representation of TAI to time stamp your logs, and you must now convert those time stamps to readable text.

Construct a base date of January 1, 1970 at 00:00:00. Add the time stamp minus 10 to it, specifying that seconds before 1972 are variable length. Convert

the result to text. The code looks like this:

```
/* Example 4: using TAI. Time_stamp_value is the TAI integer
 * that is to be converted to a readable format. */
void
example_4 (long long int time_stamp_value)
{
    struct tm time1_tm;
    struct tm time2_tm;
    char buffer1 [64];

    /* Construct the base date of 1970-01-01T00:00:00Z. */
    time_current_tm (&time1_tm);
    time1_tm.tm_year = 1970 - 1900;
    time1_tm.tm_mon = 1 - 1;
    time1_tm.tm_mday = 1;
    time1_tm.tm_hour = 0;
    time1_tm.tm_min = 0;
    time1_tm.tm_sec = 0;

    /* Add the time stamp, which is the integer representation of TAI. */
    time_copy_tm (&time1_tm, &time2_tm);
    time_UTC_add_seconds (&time2_tm, time_stamp_value - 10, 1972);
    time_tm_to_string (&time2_tm, &buffer1 [0], sizeof (buffer1));

    /* Print the result. */
    printf ("%lld TAI is %s.\n", time_stamp_value, buffer1);
    return;
}
```

If you find the use of variable-length seconds before 1972 troublesome, see the next example.

10.5 Displaying PTP time stamps

IEEE 1588, known as Precision Time Protocol or PTP, counts fixed-length seconds since an epoch. The SMPTE ST-2059-2 profile specifies that the epoch is 63 072 010 seconds before January 1, 1972 at 00:00:00 UTC. That definition avoids the complexity of variable length seconds before 1972, and is effectively the same as the TAI integer in the previous example for dates after January 1, 1972, since there are 63 072 000 variable-length seconds between January 1, 1970 and January 1, 1972.

PTP always measures fixed-length seconds, so how should we display dates between January 1, 1970 and January 1, 1972? I suggest that such times be displayed by pretending that fixed-length seconds were being used during that time. Thus, converting a PTP time to text for display will show a time that

does not correspond to contemporary civil time between January 1, 1970 and January 1, 1972.

The code is similar to the previous example, but using fixed-length seconds before 1972. The display is intended to be more readable than the ISO 8601 format used in the previous example. PTP times 15 638 408 and 47 174 409 correspond to the leap seconds that are needed to keep a count of fixed-length seconds synchronized with the rotation of the Earth.

```
/* Example 5: using PTP (IEEE 1588) with the SMPTE ST-2059-2 profile. */
void
example_5 (long long int time_stamp_value)
{
    struct tm time1_tm;
    struct tm time2_tm;
    struct tm time3_tm;
    char buffer1 [128];

    /* Construct the base date of 1972-01-01T00:00:00Z. */
    time_current_tm (&time1_tm);
    time1_tm.tm_year = 1972 - 1900;
    time1_tm.tm_mon = 1 - 1;
    time1_tm.tm_mday = 1;
    time1_tm.tm_hour = 0;
    time1_tm.tm_min = 0;
    time1_tm.tm_sec = 0;

    /* Add the time stamp, which is an integer. Note that the epoch
     * for SMPTE ST-2059-2 is 63,072,010 seconds before the base date.
     * PTP always uses fixed-length (SI) seconds. */
    time_copy_tm (&time1_tm, &time2_tm);
    time_UTC_add_seconds (&time2_tm, time_stamp_value - 63072010, INT_MIN);

    /* Convert to local time and use strftime to make a very readable
     * display. */
    time_UTC_to_local (&time2_tm, &time3_tm, INT_MIN);
    strftime (&buffer1 [0], sizeof (buffer1),
              "%A, %B %d, %Y, %I:%M:%S %p %Z", &time3_tm);

    /* Print the result. */
    printf ("PTP %lld displays as %s.\n", time_stamp_value, buffer1);
    return;
}
```

10.6 Displaying PTP time stamps using Python

We wish to display PTP time stamps as in the previous example, but we prefer to code in Python.

Example 6: Display PTP time stamps using Python.

```
import ctypes
import time
import time_subroutines

def example_6 (time_stamp_value):

    # Construct the base date of January 1, 1972, at midnight.
    time1_tm = time_subroutines.tm (
        tm_year = 1972 - 1900, tm_mon = 1 - 1, tm_mday = 1,
        tm_hour = 0, tm_min = 0, tm_sec = 0, tm_isdst = 0,
        tm_gmtoff = 0, tm_zone = None)

    # Add the time stamp, which is an integer. Note that the epoch
    # for SMPTE ST-2059-2 is 63,072,010 seconds before the base date.
    # PTP always uses fixed-length (SI) seconds.
    time2_tm = time_subroutines.tm()
    time_subroutines.time_copy_tm (time1_tm, time2_tm)
    time_subroutines.time.UTC_add_seconds (
        time2_tm, time_stamp_value - 63072010,
        time_subroutines.int_min)

    # Convert to local time.
    time3_tm = time_subroutines.tm()
    time_subroutines.time.UTC_to_local (
        time2_tm, time3_tm, time_subroutines.int_min)

    # Convert the POSIX tm structure to the Python struct_time structure.
    # Add 1900 to tm_year and 1 to tm_mon. For tm_wday, struct_time has
    # 0 meaning Monday whereas POSIX has 0 meaning Sunday, thus add 6
    # modulo 7. For tm_yday, struct_time is 1-366 whereas POSIX is 0-365,
    # so add 1.
    time4 = time.struct_time(
        (time3_tm.tm_year + 1900, time3_tm.tm_mon + 1,
         time3_tm.tm_mday, time3_tm.tm_hour,
         time3_tm.tm_min, time3_tm.tm_sec,
         (time3_tm.tm_wday + 6) % 7,
         time3_tm.tm_yday + 1, time3_tm.tm_isdst))

    # Convert to a string using strftime and print.
    buffer1 = time.strftime ("%A, %B %d, %Y, %I:%M:%S %p %Z", time4)
```

```

print ("PTP " + str(time_stamp_value) + " displays as " +
      buffer1 + ".")
return

```

10.7 Displaying Local Time in Another Time Zone

Howard E. Hinnant has an excellent package of time subroutines for C++ at this URL: <https://howardhinnant.github.io/date/tz.html>. One of his examples is displaying the local time of arrival of a flight from New York City to Tehran, leaving on December 31, 1978 at 12:01 PM local time and flying for 14 hours and 44 minutes. Local time in New York is 5 hours behind UTC and in Tehran is 3 hours 30 minutes ahead of UTC, so you might expect the plane to arrive on January 1, 1979, at 11:15, but in fact the local time of arrival is 11:14:59 because of the leap second while the plane was in flight.

Here is Python code to compute the Tehran local time of arrival, assuming it is run at the departure location.

Example 7: Compute the arrival time of a flight to Tehran.

```

import ctypes
import time
import time_subroutines

def example_7 (flight_time):

    # Construct the departure date of December 31, 1978,
    # at 12:01 local time.
    time1_tm = time_subroutines.tm()
    time_subroutines.time_current_tm(time1_tm)
    time1_tm.tm_year = 1978 - 1900
    time1_tm.tm_mon = 12 - 1
    time1_tm.tm_mday = 31
    time1_tm.tm_hour = 12
    time1_tm.tm_min = 1
    time1_tm.tm_sec = 0
    time5 = time.struct_time (
        (time1_tm.tm_year + 1900, time1_tm.tm_mon + 1,
         time1_tm.tm_mday, time1_tm.tm_hour,
         time1_tm.tm_min, time1_tm.tm_sec,
         (time1_tm.tm_wday + 6) % 7,
         time1_tm.tm_yday + 1, time1_tm.tm_isdst))
    buffer1 = time.strftime (
        "%A, %B %d, %Y, %I:%M:%S %p %Z", time5)
    print ("The flight leaves here on " + buffer1 + ".")

    # Convert to UTC.

```

```

time2_tm = time_subroutines.tm()
time_subroutines.time_local_to_UTC (
    time1_tm, time2_tm, time_subroutines.int_min)
# Add the flight time.
time3_tm = time_subroutines.tm()
time_subroutines.time_copy_tm (time2_tm, time3_tm)
time_subroutines.time_UTC_add_seconds (
    time3_tm, flight_time, time_subroutines.int_min)

# Convert to local time in Tehran.
# Tehran's time zone is +3:30.
time4_tm = time_subroutines.tm()
time_subroutines.time_UTC_to_foreign_local (
    time3_tm, ((3 * 3600) + (30 * 60)),
    time4_tm, time_subroutines.int_min)

time5 = time.struct_time(
    (time4_tm.tm_year + 1900, time4_tm.tm_mon + 1,
     time4_tm.tm_mday, time4_tm.tm_hour,
     time4_tm.tm_min, time4_tm.tm_sec,
     (time4_tm.tm_wday + 6) % 7,
     time4_tm.tm_yday + 1, time4_tm.tm_isdst))

# Convert to a string using strftime and print.
buffer1 = time.strftime (
    "%A, %B %d, %Y, %I:%M:%S %p IRST", time5)
print ("The flight arrives in Tehran on " +
    buffer1 + ".")
return

# The flight time is quoted as 14 hours and 44 minutes,
# but that assumes that all minutes are 60 seconds in length.
# In fact, the flight time is the same no matter what the
# clocks say, so we express the flight time as a number of
# seconds.
example_7 ((14 * 3600) + (44 * 60))

```

Note that this code must have the UTC offset and the abbreviation of Tehran's time zone as constants, rather than extracting them from the time zone data base, as Howard's example does.

Another good resource for time zone information is the International Components for Unicode, at <http://site.icu-project.org>. See the Date/Time Services under ICU User Guide.

11 Limitations

11.1 Unpredictable Rotation of the Earth

The rotation rate of the Earth is not predictable far in advance. It must be observed, like the weather. To say this another way, we do not know exactly when the Sun will rise a year from now. Because Coordinated Universal Time is tied to the rotation of the Earth, it is similarly uncertain.

We have increasingly good records of the rotation rate of the Earth from the time of the invention of the telescope and the pendulum clock until the present. Prior to 1825 the measurements become uncertain. Efforts have been made to improve our knowledge of the rotation rate of the Earth in historical times[3][4][8][7][2][9][5]. This software carries a table in file `extraordinary_days.dat` that reaches back to the year -2000 and forward to the year 2500 based on the latest research on the rotation of the Earth. Beyond the table, the software makes predictions which become less reliable the further out you go.

The table will be updated from time to time to capture present observations of the Earth's rotation and better estimates from historical times. If your application deals with times before 1825 or more than six months in the future, you should recompute your times whenever the DTAI table is updated. In the example of the rocket over Central Park, if you had pre-computed the times in 2015, you might have missed the leap second at the end of December 31, 2016. The update to the DTAI table in the middle of 2016 should cause the schedule for the remainder of the year to be recomputed, resulting in a launch time of 23:59:59 for the December 31 rocket, instead of 23:59:58.

If your application deals only with days, and is not sensitive to the exact number of seconds between two times, you can be more relaxed.

11.2 Only coded for GNU/Linux

The code embedded in this PDF has been written for GNU/Linux. Some effort would be required to port the code to another operating system.

12 Kernel Recommendations

Most of the work needed to handle UTC correctly is done in application programs, but some kernel changes would result in better UTC support.

1. Add a named clock, called `CLOCK_UTC`, which uses a `timeval` in which the nanoseconds field has 10^9 added to indicate a leap second. This would allow the clock to be set during a leap second.
2. Add a kernel boot parameter (perhaps in conjunction with an NTP configuration option) to specify the behavior of `CLOCK_REALTIME`. Choices are:

- (a) The same as the old behavior, where during a leap second 23:59:59 is repeated and `adjtimex` returns `TIME_OOP`. This is the default, for compatibility.
 - (b) Smeared time, where the clock begins to depart from UTC several hours before the leap second, reaches its maximum at the leap second, then returns to UTC over the next several hours. `Adjtimex` never returns `TIME_OOP` and no second is repeated. Reasonable choices for the total smear time are 24 and 48 hours. Clock smearing is used to mask leap seconds from software that isn't prepared to handle them.
 - (c) The same as `CLOCK_UTC`.
3. When file systems store their `mtime`, `atime` and `ctime`, they use the value returned by `CLOCK_REALTIME`. Provided that `CLOCK_REALTIME` is set to behave like `CLOCK_UTC` this fixes the inaccuracy of file times.

13 Future Work

The table of leap seconds will need to be updated every six months, when the IERS releases Bulletin C with a new leap second announcement. These updates can also capture the latest research on the rotation of the Earth in historical times. It would be nice if these updates could be included in the software automatically.

15 Revision History

2025-07-18 5.188.2 Adjust future leap seconds starting in 2015.

2025-07-11 5.187.2 Adjust future leap seconds starting in 2224. Update to IERS Bulletin C 70, issued July 7, 2025, which states that UTC – TAI will remain at –37 seconds for the next six months, at least.

2025-07-04 5.186.2 Adjust future leap seconds starting in 2150.

2025-06-13 5.185.2 Adjust future leap seconds starting in 2080.

2025-06-06 5.184.2 Adjust future leap seconds starting in 2194.

2025-05-30 5.183.2 Adjust future leap seconds starting in 2029. The next leap second is predicted to be a negative leap second on December 31, 2029.

2025-05-23 5.182.2 Adjust future leap seconds starting in 2208.

- 2020-02-15 4:6:1** Delay the June 2033 leap second by six months to December 2033.
- 2020-01-31 4:5:1** Delay the December 2042 leap second by six months to June 2043.
- 2020-01-25 4:4:1** Delay the June 2023 leap second by six months to December 2023 and the June 2028 leap second by six months to December 2028.
- 2020-01-11 4:3:1** Update to IERS Bulletin C 59, issued January 7, 2020. There will be no leap second at the end of June 2020.
- 2020-01-03 4:2:1** Delay the December 2022 leap second by six months to June 2023.
- 2019-12-20 4:1:1** Delay the December 2032 leap second by six months to June 2033.
- 2019-12-14 4:0:1** Add `time_test_for_disabled_adjtimex`.
- 2019-12-13 3:20:0** Delay the December 2027 leap second by six months to June 2028 and the December 2032 leap second by six months to June 2033.
- 2019-12-06 3:19:0** Delay the June 2022 leap second by six months to December 2022.
- 2019-12-02 3:18:0** Place the source RPM on github.
- 2019-11-29 3:17:0** Add a test for adjtimex not working. Mock or container bug reported in Fedora bugzilla 1778298.

- 2019-11-24 3:16:0** Remove dependency on `jdcal`, so we can build on more platforms.
- 2019-11-23 3:16:0** Delay the June 2027 leap second by six months to December 2027.
- 2019-11-16 3:15:0** Make dependence on 128-bit integers optional. Delay the June 2032 leap second by six months to December 2032.
- 2019-11-09 3:14:0** Simplify the Makefile and clean up the test programs for `rpmbuild`. Include a spec file in the tarball for two RPMs: `libtime` and `libtime-devel`. Move the source files to their own subdirectory, the example files to theirs, and the test and demo files to theirs.
- 2019-10-31 3:13:0** Delay the December 2021 leap second by six months to June 2022 and the June 2037 leap second by six months to December 2037.
- 2019-10-11 3:12:0** Delay the December 2026 leap second by six months to June 2027, and the June 2042 leap second by six months to December 2042. Improve the internal description of Julian Day Number.
- 2019-10-04 3:11:0** Delay the December 2031 leap second by six months to June 2032.
- 2019-09-20 3:10:0** Delay the June 2021 leap second by six months to December 2021.
- 2019-09-07 3:9:0** Delay the June 2026 leap second by six months to December 2026.
- 2019-08-17 3:8:0** Delay the December 2036 leap second by six months to June 2037.
- 2019-07-27 3:7:0** Update the leap seconds before 1840 based on the latest research on the rotation of the Earth.
- 2019-07-04 3:6:0** Update to IERS Bulletin C 58, issued July 4, 2019, which states that no leap second will be introduced at the end of December 2019, so `UTC - TAI` will remain at `-37` seconds for the next six months, at least.
- 2019-06-22 3:5:0** Be more careful with the definition and display of Julian Day Numbers.
- 2019-06-16 3:4:0** Delay the June 2020 leap second to June of 2021, and generally revise the leap second schedule by using a new algorithm to predict them.
- 2019-06-09 3:3:0** Delay the June 2076 leap second by six months to December of 2076.

- 2019-06-04 3:2:0** Delay the June 2036 leap second by six months to December of 2036. Say more about Python.
- 2019-05-19 3:1:0** Delay the December 2050 leap second by six months to June of 2051. Add a Python example.
- 2019-04-28 3:0:0** Add support for Python. `Int128__to__string` now takes its value argument by reference instead of by value.
- 2019-04-20 2:11:0** Delay the December 2039 leap second to June of 2040.
- 2019-04-09 2:10:0** Advance the June 2040 leap second back to December 2039. Show the predictions for the next two leap seconds.
- 2019-03-30 2:9:0** Delay the December 2039 leap second by six months to June 2040, and delay the June 2065 leap second by six months to December 2065.
- 2019-03-24 2:8:0** Return the next leap second to June 30, 2020, and adjust some of the leap second predictions for the rest of the twenty-first century.
- 2019-03-16 2:7:0** Advance the next leap second from June 30, 2020 to December 31, 2019, and adjust the leap second predictions for the rest of the century.
- 2019-01-20 2:6:0** Advance the June 2095 leap second by six months, returning it to December 2094.
- 2019-01-12 2:5:0** Update to IERS Bulletin C 57, issued January 7, 2019, which states that no leap second will be introduced at the end of June 2019, so UTC – TAI will remain at –37 seconds for the next six months, at least.
- 2018-12-23 2:4:0** Delay the December 2094 leap second by six month to June 2095.
- 2018-12-02 2:3:0** Add information on converting IEEE 1588 (PTP) times to readable text.
- 2018-12-01 2:2:0** Delay the December 2077 leap second by six months to June 2078.
- 2018-11-25 2:1:0** Improve the algorithm for anticipating future leap seconds.
- 2018-11-11 2:0:0** Changed “variable length seconds before 1972” to “variable length seconds before year”. This additional flexibility is in honor of Microsoft Windows, which will be counting leap seconds after January 1, 2019.
- 2018-10-04 1:15:0** Update the list of dependencies in the README file for Fedora 29.

- 2018-09-30 1:14:0** Improve the prediction of future leap seconds.
- 2018-09-22 1:13:0** Move the prediction of the next leap second from December 31, 2020 to June 30, 2020 based on predictions of the Earth's rotation by the IERS projected into the future.
- 2018-07-15 1:12:0** Update to IERS Bulletin C 56, issued July 5, 2018, which states that no leap second will be introduced at the end of December 2018, so UTC – TAI will remain at –37 seconds for the next six months, at least.
- 2018-05-20 1:11:0** Move the prediction of the next leap second from June 30, 2020 to December 31, 2020 based on predictions of the Earth's rotation by the IERS projected into the future.
- 2018-05-06 1:10:0** Move the prediction of the next leap second from December 31, 2020 to June 30, 2020 based on predictions of the Earth's rotation from the IERS projected into the future.
- 2018-01-15 1:9:0** Update to IERS Bulletin C 55, issued January 9, 2018, which states that no leap second will be introduced at the end of June 2018 so UTC – TAI will remain at –37 seconds for the next six months, at least.
- 2017-12-04 1:8:0** Add information about International Atomic Time.
- 2017-11-19 1:7:0** Add support for pkg-config, make check and make distcheck. Recommend CLOCK_BOOTTIME rather than CLOCK_MONOTONIC because CLOCK_MONOTONIC stops counting when the computer is suspended, and therefore can change its epoch while an application is running.
- 2017-10-08 1:6:0** Improve the MAN page.
- 2017-09-17 1:5:0** Place on github.
- 2017-08-27 1:4:0** Add a MAN page.
- 2017-07-08 1:3:0** Use Automake in the build procedure. Distribute the software using the customary GNU packaging, with the PDF file as its documentation. Continue to include the software in the PDF as embedded files. Build the PDF only if requested. Update to IERS Bulletin C 54, issued July 6, 2017, which states that no leap second will be introduced at the end of December, 2017, so UTC – TAI will remain at –37 seconds for the next six months, at least.
- 2017-05-07 1:2:0** Minor typographical changes, add test_local.c, work around compiler over-optimization in int128_to_string.
- 2017-01-27 1:1:0** Update the Makefile and some of the test programs based on feedback from Steve Summit.

2017-01-18 1:0:0 Added the ability to use variable length seconds before 1972.

2017-01-10 0:2:0 Updated to IERS Bulletin C 53, issued January 9, 2017, which states that UTC – TAI will remain at –37 seconds for the next six months, at least.

2017-01-01 0:1:0 Added a description of the `stat` function, the list of entry points and the kernel recommendations. Handle converting -2^{127} to a string.

2016-12-21 0:0:0 Original distribution.
